#### **Balanced Chemical Equation vs. Reaction Mechanism**

- A balanced equation for a chemical reaction indicates the substances present at the start of the reaction and those present at the end of the reaction. It provides no information, however, about the detailed steps that occur at the molecular level as the reactants are turned into products.
- Remember: Rate laws can only be determined **experimentally**, NOT from coefficients in the reaction. If you know the reaction mechanism, you can determine the rate law.

#### **Elementary Reactions**

- Reactions may occur all at once or through several steps known as elementary reactions.
- An elementary reaction is a chemical reaction in which one or more \_\_\_\_\_

## **Multistep Mechanisms**

The net change represented by a balanced chemical equation often occurs by a multistep mechanism consisting of a sequence of elementary reactions.

The following reaction proceeds in two elementary reactions/steps:

Step 1:  $NO_2 + NO_2 \longrightarrow NO_3 + NO$ Step 2:  $NO_3 + CO \longrightarrow NO_2 + CO_2$ 

The chemical equations for the elementary reactions in a multistep mechanism must always add to give the chemical equation of the overall process.

Overall Reaction: \_\_\_\_\_

Because NO<sub>3</sub> is neither a reactant nor a product of the overall chemical reaction—it is formed in one elementary reaction and consumed in the next—it is called an \_\_\_\_\_\_

## Practice:

1. It has been proposed that the conversion of ozone into  $O_2$  proceeds by a two-step mechanism:  $O_3(g) \longrightarrow O_2(g) + O(g)$ 

$$O_3(g) + O(g) \longrightarrow 2 O_2(g)$$

(a) Describe the molecularity of each elementary reaction in this mechanism.

(b) Write the equation for the overall reaction.

- (c) Identify the intermediate(s)
- 2. For the reaction:  $Mo(CO)_6 + P(CH_3)_3 \longrightarrow Mo(CO)_5 P(CH_3)_3 + CO$ the proposed mechanism is  $Mo(CO)_6 \longrightarrow Mo(CO)_5 + CO$

$$Mo(CO)_5 + P(CH_3)_3 \longrightarrow Mo(CO)_5 P(CH_3)_3$$

(a) Is the proposed mechanism consistent with the equation for the overall reaction?

(b) What is the molecularity of each step of the mechanism?

(c) Identify the intermediate(s).

# **Determining the Rate Law for Multi-Step Mechanisms**

- In a multistep process, each elementary step of the mechanism has its own rate constant and activation energy.
- One of the steps will be slower than all others. The overall reaction cannot occur faster than this \_\_\_\_\_\_, known as the \_\_\_\_\_\_ The \_\_\_\_\_\_ for a reaction is based on the \_\_\_\_\_\_

## Reactions with a Slow Initial Step (these are the easier ones)

Ex: Consider the two-step mechanism:

Step 1:  $NO_2(g) + NO_2(g) \xrightarrow{k_1} NO_3(g) + NO(g)$ (slow) Step 2:  $NO_3(g) + CO(g) \xrightarrow{k_2} NO_2(g) + CO_2(g)$ (fast) Overall:  $NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g)$ 

The rate-determining step is \_\_\_\_\_\_. This step is a \_\_\_\_\_\_ process, so the order of this reaction is \_\_\_\_\_\_. The rate law for the overall

reaction is just the rate law for the slow, rate-determining elementary reaction and can therefore be written as \_\_\_\_\_

Experiments can be done to confirm that [CO] does not in fact affect the reaction rate (and therefore is not included in the rate law).

## **Practice:**

1. The decomposition of nitrous oxide, N<sub>2</sub>O, is believed to occur by a two-step mechanism:  $N_2O(g) \longrightarrow N_2(g) + O(g)$  (slow)

 $N_2O(g) + O(g) \longrightarrow N_2(g) + O_2(g)$  (fast)

(a) Write the equation for the overall reaction.

(b) Write the rate law for the overall reaction

2. Ozone reacts with nitrogen dioxide to produce dinitrogen pentoxide and oxygen:

$$O_3(g) + 2 \operatorname{NO}_2(g) \longrightarrow \operatorname{N}_2O_5(g) + O_2(g)$$

The reaction is believed to occur in two steps:

 $O_3(g) + NO_2(g) \longrightarrow NO_3(g) + O_2(g)$ 

$$NO_3(g) + NO_2(g) \longrightarrow N_2O_5(g)$$

The experimental rate law is rate =  $k[O_3][NO_2]$ . What can you say about the relative rates of the two steps of the mechanism (which one is the rate determining step)?

#### Reactions with a Fast Initial Step (these are the trickier ones)

It is less straightforward to derive the rate law for a mechanism in which an intermediate is a reactant in the rate-determining step. This situation arises in multistep mechanisms when the first step is fast and therefore not the rate-determining step.

Ex: 
$$2 \operatorname{NO}(g) + \operatorname{Br}_2(g) \longrightarrow 2 \operatorname{NOBr}(g)$$
  
Step 1:  $\operatorname{NO}(g) + \operatorname{Br}_2(g) \rightleftharpoons_{k_1} \operatorname{NOBr}_2(g)$  (fast)  
Step 2:  $\operatorname{NOBr}_2(g) + \operatorname{NO}(g) \xrightarrow{k_2} 2 \operatorname{NOBr}(g)$  (slow)  
Because \_\_\_\_\_\_ is the rate-determining step, the rate law for that step governs  
the rate of the overall reaction and would be written as \_\_\_\_\_\_.

However, NOBr<sub>2</sub> is an \_\_\_\_\_\_ and not part of the overall reaction. Therefore, we need to substitute for NoBr<sub>2</sub> in the rate law equations.

You can assume step 1 is in equilibrium; the forward and reverse reactions of step 1 are occurring faster than step 2.

Set these rates equal to each other:

Rearrange to solve for NoBr<sub>2</sub>:

$$k_{1}[\text{NO}][\text{Br}_{2}] = k_{-1}[\text{NOBr}_{2}]$$
  
Rate of forward reaction  
$$[\text{NOBr}_{2}] = \frac{k_{1}}{k_{-1}}[\text{NO}][\text{Br}_{2}]$$

Substitute this into the rate law that involved the intermediate:

Rate = 
$$k_2 \frac{k_1}{k_{-1}}$$
 [NO][Br<sub>2</sub>][NO] =  $k$ [NO]<sup>2</sup>[Br<sub>2</sub>]

#### Practice:

Show that the following mechanism for  $2 \operatorname{NO}(g) + \operatorname{Br}_2(g) \longrightarrow 2 \operatorname{NOBr}(g)$ also produces a rate law consistent with the experimentally observed one

Step 1: 
$$NO(g) + NO(g) \xrightarrow{k_1} N_2O_2(g)$$
 (fast, equilibrium)  
Step 2:  $N_2O_2(g) + Br_2(g) \xrightarrow{k_2} 2 NOBr(g)$  (slow)

#### **Reaction Mechanisms Problem Set**

1. What is the molecularity of each of the following elementary reactions? Write the rate law for each.

a. 
$$\operatorname{Cl}_2(g) \longrightarrow 2 \operatorname{Cl}(g)$$

- b.  $OCl^{-}(aq) + H_2O(l) \longrightarrow HOCl(aq) + OH^{-}(aq)$
- c.  $2 \operatorname{NO}(g) \longrightarrow \operatorname{N}_2\operatorname{O}_2(g)$
- 2. Based on the following reaction profile,
  - a. How many intermediates are formed in the reaction?
  - b. How many steps are in this reaction mechanism?Which step is the rate determining step?
- 3. Consider the following mechanism.

 $\begin{array}{c} A_2 + B_2 \rightarrow R + C & (slow) \\ A_2 + R \rightarrow C & (fast) \end{array}$ 

- a. Write the overall balanced chemical equation.
- b. Identify any intermediates within the mechanism.
- c. Write the rate law for the overall reaction.
- 4. The following mechanism has been proposed for the gas phase reaction of H<sub>2</sub> with ICI:
  - a. Write the balanced equation for the overall reaction.
  - b. Identify any intermediates in the mechanism.
  - c. If the first step is slow and the second one is fast, which rate law do you expect to be observed for the overall reaction?

Reaction progress

 $\begin{array}{l} \mathrm{H}_{2}(g) \,+\, \mathrm{ICl}(g) \longrightarrow \,\mathrm{HI}(g) \,+\, \mathrm{HCl}(g) \\ \mathrm{HI}(g) \,+\, \mathrm{ICl}(g) \,\longrightarrow \,\mathrm{I}_{2}(g) \,+\, \mathrm{HCl}(g) \end{array}$ 

5. The decomposition of hydrogen peroxide is catalyzed by iodide ion. The catalyzed reaction is thought to proceed by a two-step mechanism:

$$H_2O_2(aq) + I^-(aq) \longrightarrow H_2O(l) + IO^-(aq)$$
 (slow)

 $IO^{-}(aq) + H_2O_2(aq) \longrightarrow H_2O(l) + O_2(g) + I^{-}(aq)$  (fast)

- a. Write the chemical equation for the overall process.
- b. Identify the intermediate, if any, in the mechanism.
- c. Assuming that the first step of the mechanism is rate determining, predict the rate law for the overall process.
- 6. Consider the exothermic reaction between reactants A and B:

$$A + B \rightarrow E$$
 (fast)

$$\mathbf{E} + \mathbf{B} \rightarrow \mathbf{C} + \mathbf{D}$$
 (slow)

Determine the rate law for the reaction.

7. The following mechanism has been proposed for the reaction of NO with H<sub>2</sub> to form N<sub>2</sub>O and H<sub>2</sub>O: NO(g) + NO(g)  $\longrightarrow$  N<sub>2</sub>O<sub>2</sub>(g)

 $N_2O_2(g) + H_2(g) \longrightarrow N_2O(g) + H_2O(g)$ 

- a. Show that the elementary reactions of the proposed mechanism add to provide a balanced equation for the reaction.
- b. Write a rate law for each elementary reaction in the mechanism.
- c. Identify any intermediates in the mechanism.
- d. The observed rate law is Rate =  $k[NO]^2[H_2]$ . If the proposed mechanism is correct, what can we conclude about the relative speeds of the first and second reactions?
